# Outline

- 1 Motivation
- 2 Data
- 3 Diff-in-diff methodology
- 4 Results
- 5 Model
- 6 Conclusion

# An **old** question – **new** data – a **new** result – a **newish** explanation

- ▶ How do taxes affect capital structure?
- ▶ New data on private firms in the United States

## The first part of the paper is empirical

- ▶ Use comprehensive samples of U.S. privately-held firms
- ▶ Use simple event study techniques around changes in state corporate income taxes since the late 1980s
- ▶ Distinguish between enactment and effective dates of tax changes

## The main findings contradict the importance of the tax benefit of debt

- ▶ Corporate leverage increases after tax cuts and decreases after tax hikes
- ▶ Strong results for small private firms.
- ▶ Weak results for all public firms.
- ▶ Zero sensitivity for large private firms.

## The second part of the paper is structural

- ▶ We estimate a dynamic equilibrium model of an economy
- ▶ Firms are financed by internal profits and external **risky** debt
- ▶ They hire, invest, and adjust debt in anticipation of future tax changes
- ▶ Interest expense **is** tax deductible

## We show that a tax-sensitive cost can offset the tax benefit of debt

- ▶ Tax shields make leverage more attractive
- ▶ Taxes make firms less profitable and less valuable
- ▶ They move default thresholds and credit spreads
- ▶ In the model, the **quantitative** effect of taxes on default thresholds and credit spreads can be larger

## Evidence has mostly supported the interest tax shield.

- ▶ Nearly all empirical evidence based on samples of large publicly-traded companies (Fleckenstein, Longstaff, and Strebulaev 2019)
- ▶ Taxes increase corporate borrowing (Heider and Ljungqvist 2015; Faccio and Xu 2015)

# Outline

- 1 Motivation
- 2 Data**
- 3 Diff-in-diff methodology
- 4 Results
- 5 Model
- 6 Conclusion

## Corporate loan and financial statement data

- ▶ Firm financial statements from the Federal Reserve's Y-14 Collection:
  - ▶ **Borrower** financials from the loan portfolios of the 37 largest banks in the U.S. since 2011
  - ▶ Screen for pass-through entities
  - ▶ 38,221 firm-years, 2011–2017
- ▶ Financials data on public firms comes from the CRSP-Compustat database
  - ▶ 2011–2017 with historical information on firm location

## Y14 firms are small, use more debt, and are more profitable

## Data on state corporate taxation

- ▶ Annual data on the top statutory corporate income tax rates since 1987 from Suárez Serrato and Zidar (2018). Hand collected after 2010.
- ▶ Hand collect all corresponding tax enactment dates.

# Outline

- 1 Motivation
- 2 Data
- 3 Diff-in-diff methodology**
- 4 Results
- 5 Model
- 6 Conclusion

# We start with a simple event study<sup>†</sup>

- ▶ Our base event year is  $t - 3$ .

$$y_{it} = \bar{\alpha}_i + \bar{\beta}_t + \sum_{k=-2}^{t=+4} \bar{\lambda}_k \mathbf{1}\{K_{it} = k\} + \delta \mathbf{X}_{it} + \varepsilon_{it}$$

- ▶  $y_{it}$  is an outcome
- ▶ firm fixed effects
- ▶ time fixed effects
- ▶  $K_{it}$  is the number of periods relative to the event
- ▶  $k < 0$  correspond to pre-trends
- ▶  $k \geq 0$  correspond to dynamic effects relative to the event
- ▶  $X$  contains state tax base rules/credits and local economy/firm controls

<sup>†</sup> I will talk about the recent diff-in-diff literature later

- 1 Motivation
- 2 Data
- 3 Diff-in-diff methodology
- 4 Results**
- 5 Model
- 6 Conclusion

# Tax Cuts, Y-14 Data, Enactment Dates, Small firms

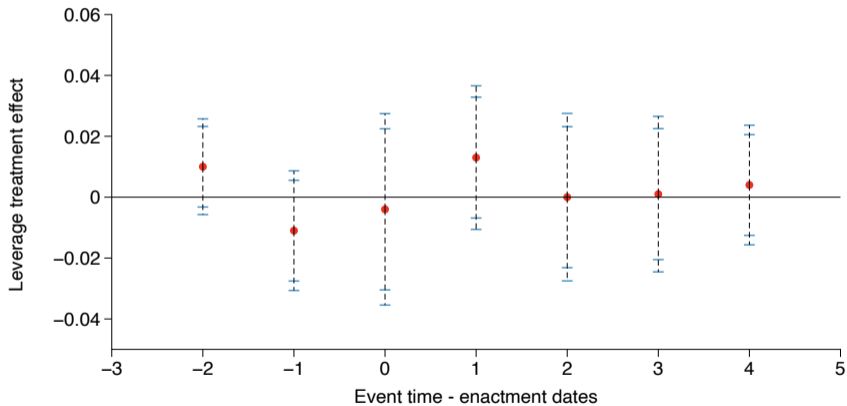

## Significant rise in year zero that persists until year four

# Tax Cuts, Y14-Data, Enactment Dates, Large firms

## Nothing to see here

# Tax Cuts, Compustat, Enactment Dates

## Almost nothing happens!

## Stuff folks worry about . . .

- ▶ Question: but aren't these just credit supply effects?
  - ▶ But then why would we see effects at the enactment date?
- ▶ Question: but aren't the effects at the enactment date just evidence for the tax shield?
  - ▶ But then why do they persist?

## Stuff folks worry about . . .

- ▶ Question: but aren't tax cuts endogenous?
  - ▶ We use a Giroud and Rauh (2019)-esque narrative approach.
  - ▶ The results for small firms at enactment dates are slightly larger.

## Stuff folks worry about . . .

- ▶ Question: but aren't these treatment effects heterogeneous?
  
- ▶ For the small firms at the enactment dates:
  - ▶ de Chaisemartin and D'Haultfoeuille (2020) offer an estimator for a single ATT:
    - ▶  $\sim 1.9\%$  effect at time 0
  
  - ▶ Sun and Abraham (2021) offer an estimator for a dynamic specification:
    - ▶ Significant positive effects at dates 0–4, slightly larger than our baseline.

# Outline

- 3 Diff-in-diff methodology
- 4 Results
- 5 Model**
- 6 Conclusion

# Equilibrium model of heterogeneous firms and a consumer

- ▶ Discrete time, infinite horizon
- ▶ A representative consumer supplies labor and consumes, maximizing expected utility, with one-period utility function

$$\ln c + \varphi(1 - n_s)$$

- ▶ Each firm maximizes the expected present value of distributions to the consumer
- ▶ The interest and wage rates adjust to clear the labor and goods markets.

## Technology is standard

- ▶ Output is a decreasing returns function of a **shock**, **capital**, and **labor**:

$$y = z^\nu (k^\alpha n^{1-\alpha})^\theta, \quad \theta < 1$$

- ▶ The shock follows an AR(1) in logs

$$\ln(z') = \rho \ln(z) + \sigma_z \varepsilon'$$

- ▶ Firms invest,  $I$ , and capital accumulates

$$k' = (1 - \delta)k + I$$

- ▶ Capital adjustment costs

$$\psi(k, k') = \frac{\psi(k' - (1 - \delta)k)^2}{2k}$$

## There are three sources of financing for investment

▶ profits are output minus payments to labor minus fixed operating costs

▶ cash (negative debt in the model)

$$p < 0$$

▶ one-period risky debt

$$p > 0$$

▶ No external equity issuance<sup>‡</sup>

<sup>‡</sup> **This is not a big deal.**

## Debt is risky

- ▶ Need not be fully collateralized
- ▶ Default occurs if debt repayment exceeds after-tax profit plus the fraction of capital,  $1 - \xi$ , that can be recovered in default
- ▶ The risky interest rate on debt is determined by a zero-profit condition for the financial intermediaries.

$$\begin{array}{l} \text{expected payoff discounted} \\ \text{at the risk free rate} \end{array} = \begin{array}{l} \text{promised payoff discounted} \\ \text{at the } \text{risky rate} \end{array}$$

## Firm profits are taxed

- ▶ Tax rate follows a persistent Markov process:

$$\tau' = \rho_{\tau}\tau + \sigma_{\tau}u', \quad u' \sim \mathcal{N}(0, 1).$$

- ▶ Interest tax deduction is baked into the model
- ▶ Government gives tax revenue to the consumer as a lump sum.
- ▶ Firms make decisions in anticipation of future tax changes.
- ▶ Estimate this process separately with a mini-SMM

## Cash flows to shareholders are inflows minus outflows

$$\begin{aligned}
 e(k, p, n, k', p', z, \tau) &= (1 - \tau) \left( z^\nu (k^\alpha n^{1-\alpha})^\theta - wn - f \right) && \text{after tax profits} \\
 &- (k' - (1 - \delta)k) - \psi(k, k') && \text{investment and adjustment costs} \\
 &+ \frac{p'}{1 + r(k', n', b', z, \tau)(1 - \tau)} - p, && \text{net debt issuance}
 \end{aligned}$$

where  $w$  is the wage rate,  
which is determined in equilibrium.

## The Bellman equation is

$$\begin{aligned}\pi(k, p, z, \tau) &= \max_{k', n, p'} \left\{ e(k, p, n, k', p', z, \tau) + \frac{1}{1+r} \mathbb{E} \pi(k', p', z', \tau') \right\} \\ e(k, p, n, k', p', z, \tau) &\geq 0\end{aligned}$$

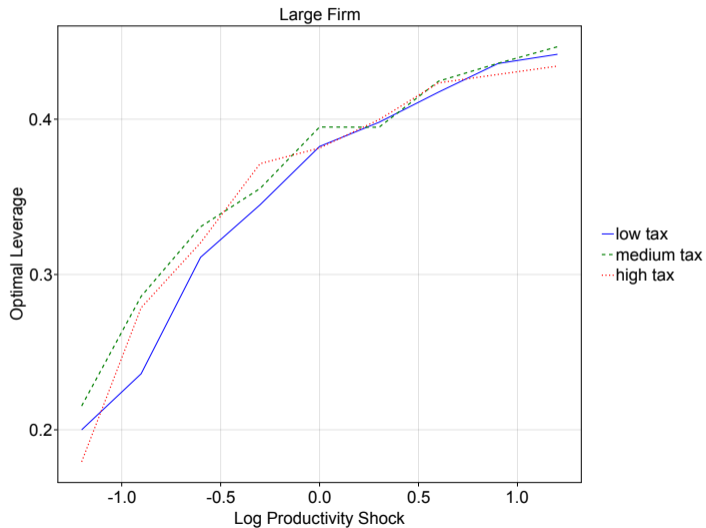

## We estimate the model and test for external validity

- ▶ Data and model moments mostly in line
- ▶ Parameter estimates standard
- ▶ Compare the estimated elasticity of leverage to staggered tax changes
- ▶ In the simulated and real data (de Chaisemartin and D'Haultfoeuille 2020)
- ▶ 0.014 versus 0.019

# Optimal leverage declines with the tax rate for small/medium firms

# Ambiguous relationship for large firms

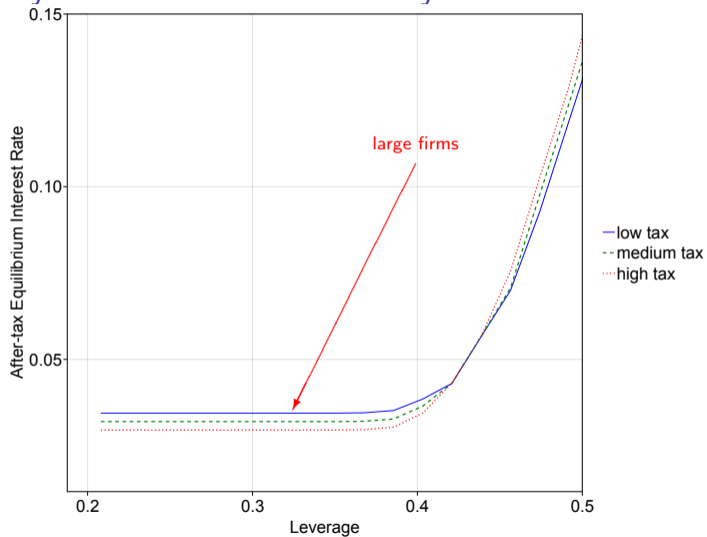

# Taxes affect risky and safe debt differently

# Taxes affect risky and safe debt differently

# Taxes affect risky and safe debt differently

## Stuff folks worry about . . .

- ▶ Question: but haven't we been doing dynamic capital structure since the late 80s?
- ▶ Why didn't anybody point this out before?
  - ▶ Yes, but those models do not have endogenous investment.
  - ▶ Firms never actively choose to be close to default thresholds.

## Stuff folks worry about ...

- ▶ Question: But do you really need this model?  
Isn't it already in the limited commitment model of Rampini and Viswanathan (2013)

- ▶ But the quantitative effect is tiny — WHY?
- ▶ The cost of debt is lost financial flexibility – not very tax sensitive

## Stuff folks worry about . . .

- ▶ Question: But isn't the default condition too stringent?
- ▶ But the same thing happens in a model with endogenous (value = 0) default

# Stuff folks worry about ...

- ▶ Question: But what if firms can issue costly equity?

## Stuff folks worry about . . .

- ▶ Question: But do you have any evidence that debt costs change with taxes?
- ▶ Yes!
  - ▶ Interest-rate data too sparsely populated.
  - ▶ Y-14 data: loan maturity and collateral requirements rise with tax cuts.
  - ▶ SNC data: internal bank credit ratings fall after tax cut enactments.

# Outline

- 1 Motivation
- 2 Data
- 3 Diff-in-diff methodology
- 4 Results
- 5 Model
- 6 Conclusion**

## Conclusion

- ▶ Revisit the relation between taxes and corporate leverage
- ▶ New data!
- ▶ Taxes have a *negative* effect on leverage
- ▶ Develop and quantify the intuition in a model
- ▶ Direct-tax benefits exist
- ▶ Can be small compared with the effect of taxes on credit spreads
